MARISASTRIDAE (RUGOSA) FROM SOUTH-EAST DEVONSHIRE, ENGLAND

by COLIN T. SCRUTTON

ABSTRACT. The family Marisastridae Różkowska 1965 is emended. Species of *Marisastrum, Haplothecia*, and *Billingsastraea?*, including *H. ogwellensis* sp. nov., are described from the Middle and Upper Devonian of south-east Devon.

THE species described in the present paper were examined in the course of a detailed consideration of the colonial phillipsastreids and related corals from south-east Devon. They belong to three different genera which are assigned to the family Marisastridae Różkowska as emended herein. Species and genera placed in the Phillipsastraeidae will be described elsewhere, together with a review of the localities from which the material was obtained.

The following abbreviations are used: BM, British Museum (Natural History); OUM, University Museum, Oxford; GS(Geol. Soc. Coll.), Geological Society Collection in the Geological Survey Museum, London; TM, Torquay Museum; TM(JB), Jukes-Browne Collection in the Torquay Museum.

Acknowledgements. This work formed part of a thesis submitted for the degree of D.Phil. at the University of Oxford, and I am indebted to the Trustees of the Burdett-Coutts Research Studentships for financial support. I would like to thank Professor Maria Różkowska (Poznàn, Poland) for lengthy discussions on the taxonomy of these and other Devonian corals, and Dr. P. Semenoff-Tian-Chansky (Muséum National d'Histoire Naturelle, Paris) for arranging the loan of topotypes of *Marisastrum marmini*. Aspects of this paper have also been discussed with Dr. W. A. Oliver Jr. (U.S. National Museum, Washington) and with Dr. H. Dighton Thomas (British Museum (Nat. Hist.)), who read and commented on the manuscript. The photographs were prepared by Mr. N. Tanti at the British Museum (Nat. Hist.).

SYSTEMATIC PALAEONTOLOGY

The genus *Marisastrum* was erected by Różkowska (1965, p. 262) with *Cyathophyllum* sedgwicki Edwards and Haime as type species. At the same time she proposed (p. 261) the family Marisastridae to include the new genus and *Ceratophyllum* Gürich. Różkowska gave the principal diagnostic features of the family as possession of a full trabecular fan based on a reflexed dissepimentarium, the absence of horseshoe dissepiments, and the presence of an epitheca. She regarded the family as belonging to the Phillipsastraeacea sensu Schouppé 1958.

Różkowska laid stress on corallite wall structure in her familial classification. In the writer's opinion, however, this factor is not of sufficient importance to justify such usage, although it may be of some significance at the generic level. Thus, some species may have an epitheca in some parts and a pseudotheca, or a complete lack of any wall structures, in others. *Phillipsastrea lacunosum* (Gürich), interpreted by Różkowska (1953, p. 45, pl. 6, figs. 3, 4) as secondarily phaceloid, is one example; another is *Phillipsastrea cincta* Smith (1945, p. 43, pl. 22, figs. 4a-c), a rather remarkable coral in which a well-formed

[Palaeontology, Vol. 10, Part 2, 1967, pp. 266-79, pls. 40-43]

epitheca is present between some corallites whilst others are united by dissepimental tissue only.

The form of the disseptimentarium in these corals appears to be the most important factor in classification at the family level. This is now recognized by most workers in separating the horseshoe-bearing phillipsastreids from the disphyllids with normal disseptiments. On the other hand, the large group of corals with reflexed disseptimentaria (and consequent broad trabecular fans) but without horseshoes have not been so clearly distinguished. Schouppé (1958), Strusz (1965), and Różkowska (1965) have all given different interpretations of their importance and classification. Schouppé (1958, p. 217) included forms with trabecular fans, both with and without horseshoe disseptments, in the suborder Phillipsastraeacea. He put all the species he considered to lack horseshoe disseptiments, however, in one genus, Billingsastraea, which he classified with Phillipsastrea in the same family. Billingsastraea as thus interpreted by Schouppé (1958, p. 235) was a collection of species belonging to at least three different genera-Billingsastraea sensu stricto, Marisastrum, and the 'Phillipsastrea' pentagona group, which will be discussed in detail elsewhere. Strusz (1965, p. 523) did not mention the suborder Phillipsastraeacea but separated the horseshoe-bearing genera in the family Phacellophyllidae. He drew attention to the group of corals with reflexed dissepimentaria lacking horseshoes as having trabeculae developed in 'disphylloid' fans. He did not distinguish them at the family level, however, but classified them with the disphyllids sensu stricto (having trabecular 'half-fans') in the family Disphyllidae.

Różkowska (1965, p. 261) was thus first to give family status to part of the group of corals with 'disphylloid' fans by erecting the Marisastridae. The writer believes, however, that the family should include all the genera with this basic dissepimental plan, irrespective of wall structure, and the family diagnosis is emended accordingly. It is doubtful whether the phillipsastreids and marisastrids form a group of sufficient importance and definition to warrant a separate suborder and for this reason the use of the Phillipsastreacea is discontinued here.

Family MARISASTRIDAE Różkowska 1965 emend.

1965 Marisastridae Różkowska, p. 261. *e.p.* 1965 Disphyllidae; Strusz, p. 525.

Type genus. Marisastrum Różkowska 1965, p. 262.

Diagnosis. Simple, fasciculate, or massive rugose corals; the latter may be cerioid, astraeoid, or thamnasterioid. Septa of two orders, major and minor, usually with spindle-shaped dilatation. Dissepimentarium reflexed. Septal trabeculae arranged in a broad fan on the dissepimental surface. No horseshoe dissepiments.

Included genera. Marisastrum Różkowska 1965; Ceratophyllum Gürich 1896 (sensu Różkowska 1965); Haplothecia Frech 1885; Billingsastraea Grabau 1917; Paradisphyllum Strusz 1965; e.p. Mansuyphyllum Fontaine 1961 sensu Strusz 1965.

Genus MARISASTRUM Różkowska 1965

 - 1965 Marisastrum sedgwicki (Edwards and Haime); Różkowska, p. 262, text-figs. 1, 2.

Lectotype (see Soshkina 1951, p. 96). The original of Edwards and Haime (1853, pl. 52, figs. 3, 3*a*), which is BM 48451. The specimen is labelled 'Middle Devonian, Torquay' and was found on 'Babba-combe Beach' according to Edwards and Haime; it is almost certainly a beach pebble.

Diagnosis and description. See Moenke 1954, p. 465; Różkowska 1965, p. 263.

Remarks. The opportunity is taken here to figure the lectotype of *Marisastrum sedg-wicki*. As Różkowska suggests, this specimen, judging by the known European distribution of the species, is probably derived from the Frasnian. However, the species has never been recorded *in situ* from England, all the known material being, like the lectotype, cut from beach pebbles.

Measurements of diameter and septal number made on the lectotype and BM 15269 (figured Różkowska 1965, fig. 1) are summarized in Table 1.

 - 1961 Hexagonaria marmini (Edwards and Haime); Semenoff-Tian-Chansky, p. 299.

Type material. The specimens figured by Edwards and Haime (1851) appear to be lost. There are, however, three topotypic specimens in the Milne Edwards Collection at the Muséum National d'Histoire Naturelle (Z63b (2 specimens) and Z63e) which agree closely with their figures 2 and 2*a* and which have been compared with the English material. The polished slab figured by Edwards and Haime (1853) from Torquay also appears to be missing.

Diagnosis. Marisastrum with non-carinate, moderately dilated spindle-shaped septa. Mean tabularium diameter about 5 mm. with between 18 and 21 major septa; ratio of tabularium to corallite area high. Increase peripheral and non-parricidal.

Description. Marisastrum marmini occurs as cerioid colonies of variable size. Most of the present specimens, from impure limestone, appear to be colonies only 5 to 10 cm. in diameter. Weathered calices have a wide central pit surrounded by a narrow reflexed platform.

Corallites are separated by a straight, or somewhat zigzagged epitheca which varies between 0.15 and 0.25 mm. in thickness. In very rare instances, however, it may fail to form between adjacent calices. A thin, dark, median line, the axial plane of Flower (1961, p. 26), can be seen where the epitheca is well preserved.

The septa are of two orders, major and minor, and may be slightly expanded at the epitheca. Usually there is a zone of septal dilatation about one-third to one-half the distance to the axis. The thickening is normally spindle-shaped, up to 0.4 or 0.5 mm. thickness, although rarely the septa may widen abruptly and taper towards the axis. When the zone of thickening approaches the epitheca, the septa may become wedge-rather than spindle-shaped. The major septa are very thin in the tabularium, with their ends slightly withdrawn from the axis and occasionally deflected in a weak vortex. The minor septa reach half-way, or somewhat less, to the axis and are less dilated than the major. The septa are non-carinate.

Horizontal tissue is generally well spaced in cross-section but appears more crowded in the zone of septal thickening. The tabularium junction is not clearly defined but corresponds approximately to the inner edge of this zone.

In longitudinal-section, the dissepimentarium is composed of several series of wellarched dissepiments. Their arrangement is somewhat variable but in the larger corallites they dip outwardly in a narrow peripheral zone. From the crest of the dissepimentarium flatter dissepiments slope steeply into the tabularium. On this reflexed surface, the septal trabeculae are arranged in a broad asymmetric fan. In immature corallites the dissepimentarium is very narrow and the dissepiments slope towards the axis throughout.

The tabulae are incomplete. There is an axial series of broad flat plates, frequently with downturned peripheral edges, which may occupy from one-half to nearly the whole

PALAEONTOLOGY, VOLUME 10

diameter of the tabularium. In the peripheral zone, horizontal, distally concave tabulae are irregularly developed.

Increase is peripheral and non-parricidal. Daughter corallites arise in the dissepimental tissue of the parent and may not form an epitheca until a late stage in their development.

Measurements of diameter and septal number are summarized in Table 1.

TABLE 1. C	omparat	tive data for species	s of <i>Marisastrum</i>
	N	M. sedgwicki 2	M. marmini 4
d_t (mm.)	O.R.	$3 \cdot 2 - 4 \cdot 2$ $3 \cdot 7$	4.3-6.2
п	0.R.	15–17	18-21
A_t/A	\overline{X}	0.13	0.2

 d_t , tabularium diameter; *n*, number of major septa; A_t/A , ratio of tabularium to corallite area. *N*, number of colonies; *O.R.*, overall range; \bar{x} , arithmetic mean.

Discussion. Edwards and Haime (1851, p. 386; 1853, p. 231) included both fasciculate and cerioid forms in their original diagnosis but the species is here limited to the latter. The diameter of the corallites and the number of septa as stated by them agree closely with measurements made on the present material.

The specimens figured by Soshkina (1951, pl. 18, figs. 3, 4; 1952, pl. 41, fig. 144 (upper two illustrations only); 1954, pl. 10, fig. 1) as '*Phillipsastraea sedgwicki*' appear to be very close to the present material. They are certainly more similar to *Marisastrum marunini* than to *M. sedgwicki* but cannot be definitely identified as conspecific with the former.

M. marmiui differs strongly from *M. sedgwicki*. The former has considerably larger tabularia and a high ratio of tabularium to corallite area (see Table 1); in addition, the septa are non-carinate. Of the species described by Moenke (1954) as *Hexagonaria*, all but her *H. hexagona* and *H. basaltiformis* should be assigned to *Marisastrum*. *M. phillipsastraeiformis* (Moenke) differs from *M. marmini* through strong carination of the septa. The other species, *M. mirabilis* (Moenke), *M. sanctacrucensis* (Moenke), and *M. davidsoni* (Edwards and Haime) *sensu* Moenke (1954) are all readily distinguished from *M. marmini*, particularly by their lower ratios of tabularium to corallite area.

M. marmini is recorded from the Frasnian of Ferques, near Boulogne, France; from the lens of Givetian or Frasnian limestone at Sidi Daoud, Chénoua, Algeria; from Frasnian limestones and beach pebbles from South Devonshire, England; and possibly also from the Frasnian of the Russian Platform and the southern Urals, U.S.S.R.

Measured material. BM R46096–9. All from thin-bedded limestones near the southern end of Saltern Cove (SX 89505842), near Paignton, South Devon; Frasnian.

Genus HAPLOTHECIA Frech 1885

- 1885 Haplothecia Frech, p. 68.

- 1940 Haplothecia; Lang, Smith, and Thomas, p. 65.
- e.p. 1951 Phillipsastraea; Soshkina, p. 95.
- e.p. 1952 Phillipsastraea; Soshkina, p. 101.
 - 1956 Haplothecia; Hill, p. 280.
- e.p. 1958 Phillipsastraea; Schouppé, p. 233.
- e.p. 1960 Phillipsastraea; Spassky, p. 65.

270

Type species. Haplothecia filata (Schlotheim); Frech 1885, p. 68, pl. 6, figs. 7, 7a = Madreporites *filatus* Schlotheim *partim* (var.) \propto 1820, p. 359.

Diagnosis. Colonial rugose corals, cerioid or astraeoid. Septa of two orders, more or less dilated against the tabularium boundary. Septa strongly carinate, usually degenerating to perforate or spongy tissue at the corallite margin. Dissepiments small, well arched; dissepimentarium surface strongly reflexed. Tabulae complete or incomplete, predominantly distally concave.

Discussion. In his original diagnosis, Frech (1885, p. 68) stressed the carination of the septa and the peculiar character of the wall separating the corallites. Lang and Smith (1935, p. 549) also discussed the carination of the septa in *Haplothecia*, comparing that in the type species with the septal structure in '*Phillipsastraea pengellyi*'. They regarded *Haplothecia* as congeneric with *Phillipsastrea* although they thought that '... it may be found desirable in the future to retain the name, perhaps as a genomorph, for the forms exhibiting the peculiar septal degeneration ...'. Their conclusion was, in effect, based on their belief that the species *pengellyi* differed from *Phillipsastrea sensu stricto* only through the character of the septa. I agree with their implication that *H. filata* and '*P*'. *pengellyi* are congeneric, but consider both distinct from *Phillipsastrea*.

The latter genus should be restricted to forms possessing horseshoe dissepiments. Schouppé (1958, p. 235) was similarly of this opinion but he claimed that horseshoe dissepiments are also developed in the type species of *Haplothecia*. He wrote (op. cit., p. 203) that 'by reason of the existence of horseshoes and the corresponding basic structure, I thus regard *Haplothecia* as a synonym of *Phillipsastr*. d'Orb., 1849 sensu'. On careful examination, however, Schlotheim's original specimen of *Madreporites filatus* (var.) α (see Pl. 41, fig. 2) shows no sign of horseshoe dissepiments.

For this reason, *Haplothecia* is here regarded as not closely related to *Phillipsastrea* and is placed in a different family. Within the Marisastridae, *Haplothecia* is distinguished by its peculiar septal structure and the dominance of distally concave plates in the tabularium.

Distribution. Frasnian of Germany (Harz) and U.S.S.R. (Urals); upper Givetian and Frasnian of south-west England.

Haplothecia filata (Schlotheim) 1820

1935 Phillipsastraea filata (Schlotheim); Lang and Smith, p. 549.

uou 1951 Phillipsastraea filata (Schlotheim); Soshkina, p. 98, text-fig. 36, pl. 18, fig. 1.

non 1952 Phillipsastraea filata (Schlotheim); Soshkina, p. 101, pl. 42, fig. 141.

uou 1960 Phillipsastraea filata (Schlotheim); Spassky, p. 66, pl. 25, figs. 3, 4.

Lectotype (see Frech 1885, p. 68). The original of *Madreporites filatus* Schlotheim (var.) α 1820, p. 359, which is in the collections of the Institut für Paläontologie und Museum der Humboldt-Universität, East Berlin. From Ibergerkalk, Bad Grund, Harz, Germany; Frasnian.

Diagnosis. Cerioid *Haplothecia* with tabularium diameters ranging from 1.4 mm. to 2.0 mm. and with 11 to 15 major septa. Septa strongly carinate and failing between the carinae peripherally. Dissepiments small, globose. Tabulae incomplete, horizontal, and distally concave.

Description. Cerioid colony with a straight, rarely zigzagged epitheca. The axial plane of Flower (1961, p. 26) is clearly seen.

Septa strongly carinate in the dissepimentarium. Towards the periphery the carinae become irregular in form and distribution and the septa frequently bifurcate. The carinae are often connected by clear structureless calcite but, towards the periphery in particular, the septa are discontinuous. The minor septa do not enter the tabularium but the major continue, smoothly attenuated, to the axis. Here there may be some fusion between adjacent or opposite septal ends.

In cross-section, the disseptimental tissue appears somewhat crowded and, particularly in the peripheral parts, rather irregular in shape.

In longitudinal-section, the dissepiments are small, globose, and evenly developed. The dissepimentarium surface is strongly reflexed, and upon it the septal trabeculae are arranged in a broad fan. The tabularium is composed of horizontal, incomplete, distally concave tabulae. Any axial structure is obscured by septal traces.

Measurements of tabularium diameter and septal number made on the lectotype are summarized in Table 2.

Discussion. The brief description above is based on the lectotype only. It is included here as this specimen has not been described since Frech (1885, p. 68), and for comparison with the English species of *Haplothecia*.

The species is only so far definitely known from the Ibergerkalk in the German Harz. The specimen figured by Soshkina (1951, pl. 18, fig. 1; 1952, pl. 42, fig. 141) is not conspecific with *H. filata*, although very similar to it and undoubtedly congeneric.

Haplothecia ogwellensis sp. nov.

Plate 41, figs. 3-6

Holotype. OUM D542; Lower Frasnian limestones, road cutting, 40 yd. west of Ramsleigh quarry entrance (SX 84417005), East Ogwell, near Newton Abbot, south Devon.

Diagnosis. Cerioid *Haplothecia* with mean tabularium diameter 1.9 mm. and with between 10 and 14 major septa. Septa strongly carinate, rarely discontinuous peripherally. Disseptiments small, well arched. Tabulae incomplete with a narrow axial series of domeshaped plates.

Description. The colonies, the external features of which are unknown, are apparently cerioid although recrystallization obscures the structure of the wall. This is usually strongly zigzagged, delimiting polygonal corallites. Only rarely does the wall break down for a short length of the corallite margin.

EXPLANATION OF PLATE 41

SCRUTTON, Devonian Marisastridae

The septa, major and minor, are 0.05 mm. thick peripherally and straight to slightly flexed in the dissepimentarium. They are variably dilated, up to c. 0.2 mm. thickness, against the tabularium boundary. Some major septa, however, may be virtually unthickened and the minor septa, which do not enter the tabularium, are less dilated than the major and frequently uniformly attenuated throughout. The major septa taper in the tabularium to 0.02–0.04 mm. width. Their axial ends may curve sharply to become confluent with septa in the adjacent quadrant, or they may be free, or rarely fused in small groups. An axial area, 0.5 to 0.25 mm. in diameter, is usually clear of septa.

The septa are variably carinate, usually with five carinae, 0.15 to 0.2 mm. wide, developed in 1 mm. of septal length. Normally the carinae are separated by clear structureless calcite but rarely this is missing and the septa are discontinuous.

Disseptiments are commonly uniserial between adjacent septa. In cross-section, the tabularium boundary is clearly but not sharply defined.

In longitudinal-section, the dissepiments are small, well arched, and between 0.1 and 0.3 mm. apart vertically. The surface of the dissepimentarium is reflexed with the crest c. 0.5 mm. outside the tabularium junction. The swollen isolated trabeculae forming the carinae are arranged in an asymmetric fan on the dissepimental surface, bending over to enter the tabularium almost horizontally.

The tabulae are mainly incomplete. There is a peripheral horizontal series of flat to distally concave tabulae, with an axial series, one-third to one-quarter of the tabularium diameter across, of dome-shaped plates. The latter appear to be fairly continuous but unfortunately they are usually partially obscured by the traces of major septa.

Quantitative data for this species are summarized in Table 2.

At/A	\overline{X}	0.06	0.095	0.1

TABLE 2. Comparative data for species of *Haplothecia* (for symbols see Table 1)

Discussion. Haplothecia ogwellensis is very similar in general appearance to *H. filata.* The limited data available for these two species (Table 2) show the most striking difference in the ratios of tabularium to corallite area. This contrast is immediately apparent on a cursory inspection of the two species. They also show slight differences in tabularium size and number of major septa but the variation in both species is virtually unknown due to lack of material.

H. ogwellensis also differs from *H. filata* in having a zigzagged wall separating the corallites as opposed to the straight epitheca of the latter. In addition, carination and septal degeneration is stronger in *H. filata* and begins to approach that seen in *H. pengellyi*.

H. ogwellensis is known so far only from the type locality.

Measured material. OUM D542-3.

non 1952 Phillipsastraea pengelli (Edwards and Haime); Soshkina, p. 102, pl. 41, fig. 146.

Lectotype (see Soshkina 1951, p. 100). The original of Edwards and Haime 1853, pl. 55, fig. 1; unfortunately this specimen is lost.

In their original description of the species, Edwards and Haime (1851, p. 422) quoted as synonymous Lonsdale's (1840, pl. 58) fig. 3*a*. Smith (1917, p. 289) was of the opinion that GS (Geol.Soc.Coll.) 6192 (Pl. 42, fig. 1) was probably the specimen figured by Lonsdale, although this cannot be definitely proved. If, however, Smith is correct, GS(Geol.Soc.Coll.) 6192 appears to be the only survivor of the original syntypes.

The lectotype was stated by Edwards and Haime to come from the Devonian of Torquay, south Devon.

Diagnosis. Astraeoid tending to thamnasterioid *Haplothecia* with tabularium diameter ranging from 2.0 to 4.9 mm. and between 13 and 24 major septa. Septa heavily carinate, usually degenerating at the periphery to a spongy state. Dissepiments small, globose; dissepimentarium surface strongly reflexed. Tabulae incomplete.

Description. The colonies, of which the external features are unknown, are astraeoid tending to thamnasterioid. The margins of individual corallites are usually indicated by a sharp geniculation of the peripheral septal ends although these seldom join together to form a distinct pseudotheca. The septa are irregularly, rarely perfectly, confluent from one corallite to the next. Varying degrees of peripheral septal break-down contribute to the diffuse nature of the pseudotheca.

The septa, both major and minor, exhibit excessive degeneration in the dissepimentarium characteristic of the species. Usually the septa are thick and solid only in a zone surrounding the tabularium where their width varies between 0.2 and 0.5 mm. In this zone septa may apparently be uni- or multi-trabecular. Peripherally, the trabeculae become separated, causing the septa to become strongly and irregularly carinate. The carinae are usually of the yard-arm type but may be xyloid when thickened trabeculae alternate on either side of the septal axis. Frequently individual trabeculae become completely isolated at the periphery with up to four across the septal width.

The character and extent of the septal degeneration is highly variable both within and between colonies. Some septa are uniformly thin with a light yard-arm carination of c. 0.2 mm. width throughout the dissepimentarium. In others, separation and isolation of the trabeculae towards the corallite margins may form a spongy mass of tissue up to 1 mm. in width.

The minor septa penetrate slightly into the tabularium but the major become smoothly attenuate and continue, c. 0.07 mm. thick, more or less to the axis. The axial ends of the

EXPLANATION OF PLATE 42

Figs. 1–5. *Haplothecia pengellyi* (Edwards and Haime). 1, Cross-section of suggested syntype, GS(Geol. Soc.Coll.) 6192, × 3. 2, Cross-section, BM R23257. × 3. 3, 4, Longitudinal-sections, BM R23257, × 4. 5, Cross-section, BM R23252, × 3. All from upper Givetian limestone, Barton quarry, Torquay, south Devon.
